

# App-Development Fundamentals

# **Transaction Family**

### **Transaction Family**

- The client, TP and state of an application is together called a Transaction Family
- Family is uniquely identified by its name and version
- A Family will have a set of addresses to set state values

# **Private and Public Key**

private key

large, randomly generated number

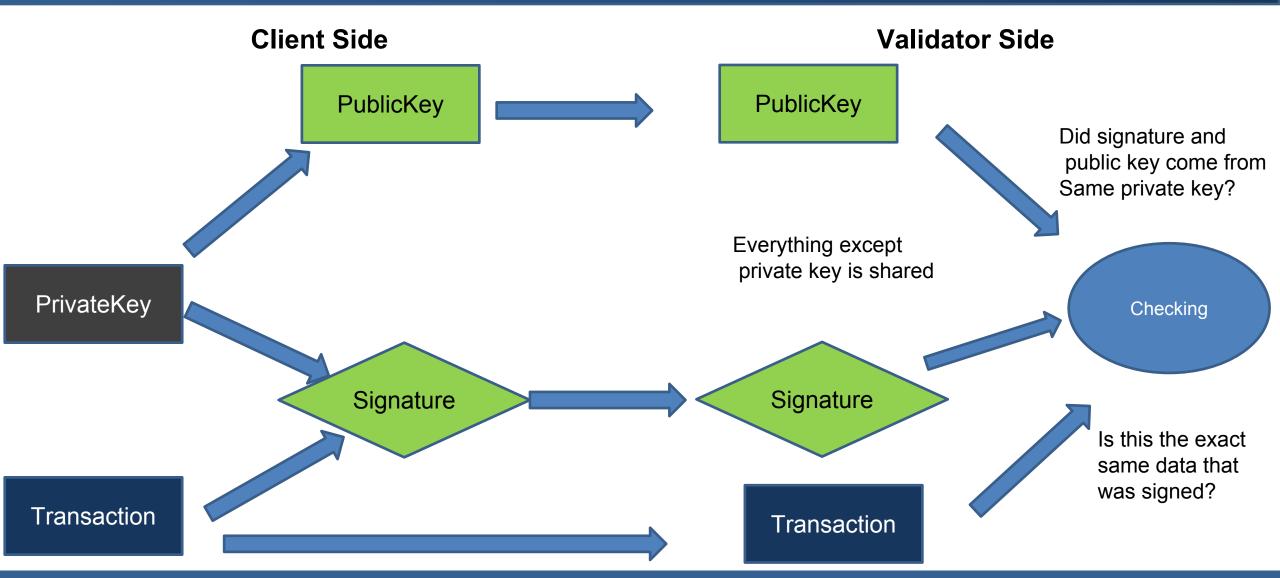

public key

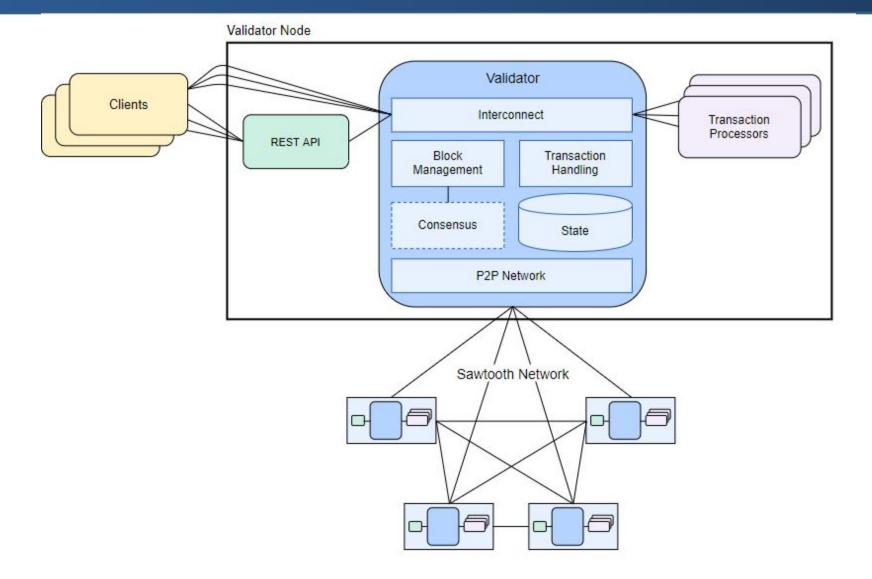

generated from the private key

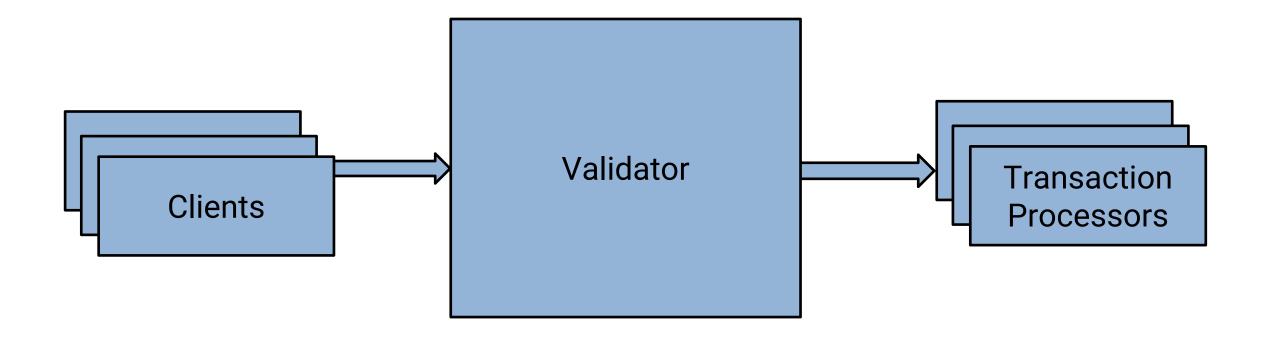

# Signing (Secp256k1 -ECDSA)

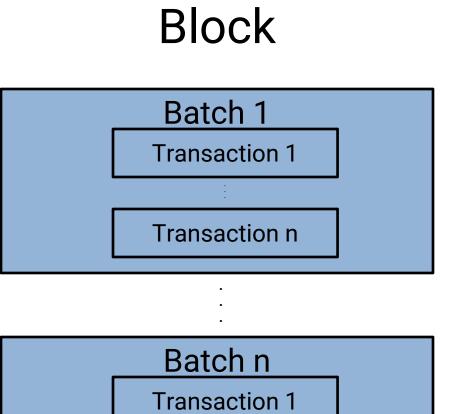

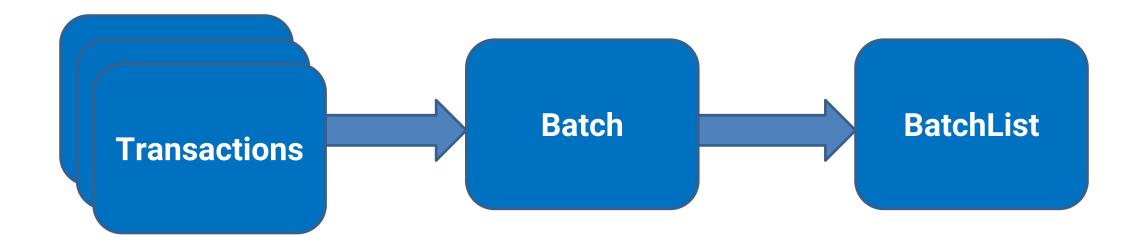

Transaction n

### State

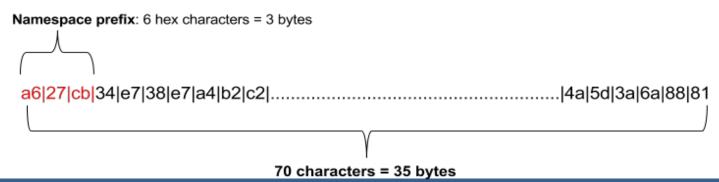

- State is where you can keep application specific data.
- State root hash is added in the block to make sure all validators have same global state
- State store works as a key/value mapping, where key is a 35 byte address and value is your application data

| Key | Value            |
|-----|------------------|
| K1  | AAA,BBB,CCC      |
| K2  | AAA,BBB          |
| K3  | AAA,DDD          |
| K4  | AAA,2,01/01/2015 |
| K5  | 3,ZZZ,5623       |

### Addressing scheme

- By convention, the first three bytes of address is formed by hashing the transaction family name (namespace)
  - That means all 35 byte address whose first three bytes is the hash a family name belongs to that transaction family
  - o ie in effect a transaction family will have 2^(32\*8) address locations available in the state
- How the addresses are split within a transaction family namespace is upto the application
- Sawtooth addresses are 70 hex characters long (35 bytes)

### Serialization and Protobuf

#### **Protocol Buffers**

Protocol buffers are a language-neutral, platform-neutral extensible mechanism for serializing structured data.

### .proto files

Stored inside: sawtooth-core/protos

### Message.encode()

encodes a message instance or valid plain JavaScript object.

### Message.create()

creates a new **message instance** from a set of properties that satisfy the requirements of a valid message.
